Abstract

School accountability systems in the United States have been criticized on a number of fronts, mainly on grounds of completeness and fairness. This study examines an alternative school quality framework—one that seemingly responds to several core critiques of present accountability systems. Examining results from a pilot study in a diverse urban district, we find that this alternative system captures domains of school quality that are not reflected in the current state system, specifically those measuring opportunity to learn and socioemotional factors. Furthermore, we find a less deterministic relationship between school quality and poverty under the alternative system. We explore the policy implications of these findings vis-à-vis the future of accountability.

Keywords

accountability, equity, school quality

Over the past two decades, policy leaders have established educational measurement and accountability systems in all 50 states. These systems are intended to help policymakers identify schools in need of support and intervention, to inform and empower the public, and to establish clear and consistent goals for educators and school leaders.

Whatever their successes, however, these systems continue to face a number of challenges, particularly with regard to capturing the multifaceted nature of school quality. Schools serve many purposes and advance multiple aims through a variety of interconnected practices (Schneider, 2017; Figlio & Loeb, 2011; Ladd & Loeb, 2013; Rothstein & Jacobsen, 2006). For political and practical reasons, however, current data systems have generally focused on a set of fairly basic outputs, important among them being student-standardized test scores in math and English. As a result, these measurement and accountability systems have been roundly criticized—for failing to capture the full picture of school quality, for relying too heavily on measures linked to student demography, and for producing a range of unintended consequences such as curricular narrowing and teaching-to-the-test (e.g., ASCD, 2014; Cowley, 2006; Darling-Hammond, 2004; National Education Association [NEA], 2011; Spalding, 2014).

Our study examines the pilot year of a holistic school quality measurement system built for a mid-sized, highly diverse urban district in Massachusetts. Constructed with stakeholder input and responding to several common criticisms of present efforts to measure school quality, this system represents a model of what accountability systems of the future might look like. Insofar as that is the case, analysis of it may help answer some of the key questions policymakers face as they revisit state-level measurement and accountability systems under the Every Student Succeeds Act (ESSA).

Ultimately, our analyses reveal that although there is some correlation between the current state accountability ratings and the ratings generated by a more comprehensive set of data, the inclusion of additional measures can dramatically alter the overall interpretation of school quality. As we find, measurement and accountability systems that draw mainly on achievement scores in math and English incompletely capture school performance, strongly reflect demographic variables, and consequently may foster the mistaken view that school quality is a uniform concept. In short, although a more holistic approach to measurement does not represent a perfect solution, it does appear to offer a much more viable basis for future accountability systems.

Literature Review

Current Data Collection and Reporting Practices

No Child Left Behind (NCLB) dramatically expanded the amount of information collected by states about school and district performance, using student outcomes to construct accountability systems with meaningful consequences. Specifically, the law required states to collect and report data

on achievement and teacher quality, and to disaggregate data by student subgroups (U.S. Department of Education [USED], 2013). Over the next decade, schools and districts bristled under NCLB, and scholars highlighted a broad range of flaws in the law. Ultimately, the USED responded by initiating a waiver process that led to significant changes in accountability in many states, such as the elimination of requirements surrounding Adequate Yearly Progress and the goal of 100% proficiency. Although waivers were granted to many states, they largely served to limit and structure data collection and reporting, rather than to expand or reimagine those enterprises. Consequently, despite other significant variance across states with regard to education, data collection and reporting practices continued to display striking similarity. As Mikulecky and Christie reported in 2014, all states incorporated student achievement and graduation rates into school accountability systems, with a majority including student growth, gap closure, and proxies for postsecondary and career readiness. This largely remains the case under ESSA, which replaced NCLB in late 2015, though states continue to revise their accountability frameworks in preparation for the 2017-2018 school year when the law will go into full effect.

State measurement and accountability systems do, of course, include more than just test scores in math and English. Still, these systems largely fail to address the full range of what schools do. Several core subjects, for instance, go untested, and therefore unmeasured. Current measurement and accountability systems largely ignore aspects of student physical, social, and emotional health emphasized by schools (Schneider, 2017; Downey, von Hippel, & Hughes, 2008; Mintrop & Sunderman, 2009). And, these systems largely fail to provide information that might lead to meaningful improvements in curriculum, teacher preparation, and school resources (Darling-Hammond, 2007). Moreover, research suggests that various elements of school quality are not intrinsically aligned, indicating that a measurement system designed to capture some elements of school quality will not necessarily capture others (e.g., Rumberger & Palardy, 2005).

Current measurement and accountability systems have also been criticized for measuring factors that are not largely under the control of schools. As research has revealed, student standardized test scores tend to correlate strongly with student demographic characteristics (Davis-Kean, 2005; Reardon, 2011), and school rankings tend to correlate strongly with school-level poverty (Spalding, 2014). Consequently, test-based outcome variables may tell stakeholders less about school performance than about families and neighborhoods. Insofar as that is the case, such data offer little in the way of actionable information, and may unnecessarily stigmatize schools with diverse student bodies.

Finally, because measurement and accountability systems shape school and district goals and activities, researchers have also explored the degree to which narrow conceptions of school quality have produced troubling unintended consequences. As scholars have shown, current systems have led to narrowing of the curriculum and an increased emphasis on test preparation (Dee, Jacob, & Schwartz, 2013; Hamilton et al., 2007; Jennings & Bearak, 2014). In addition, such systems have fostered an environment in which teachers are less satisfied with their jobs (Markow & Pieters, 2012), and in which students exhibit higher levels of stress (Segool, Carlson, Goforth, von der Embse, & Barterian, 2013).

Measurement and accountability systems remain in place as cornerstones of governance, and ESSA, like NCLB before it, continues to place significant weight on achievement scores and graduation rates in school performance rankings. That said, there are two primary reasons to suspect that data systems will change under the new law: First, ESSA stipulates that states must use an additional metric in tracking student success—a measure such as student engagement, school climate, or access to advanced coursework. Second, the additional flexibility in ESSA, both real and perceived, is likely to spur reforms in areas that have been unpopular with educators or that have triggered scholarly criticism. Influential groups such as ASCD and the NEA have strongly advocated for the inclusion of multiple measures in determinations of school success (ASCD, 2014; NEA, 2011), as have prominent academics (e.g., Darling-Hammond et al., 2016).

Emerging Efforts to Measure School Quality More Comprehensively

What other dimensions of school quality, beyond achievement results in math and English, might be measured? And what is the relationship between those new measures and the test scores that presently dominate state accountability systems?

Much discussion has revolved around Opportunity to Learn (OTL) measures, which are presumably less closely tied to student demography and more informative about what is going on inside schools. Model OTL frameworks, like that of the National Council for Teacher Education, tend to emphasize school culture, teaching environment, learning resources, and resources from the community (National Council of Teachers of English, 2012).

There has also been a great deal of discussion about expanding measurement to include Social and Emotional Learning (SEL). For the past two decades, groups such as the Collaborative for Academic, Social, and Emotional Learning (CASEL) have been advocating for a greater emphasis

on so SEL, as have organizations such as the National Association of State Boards of Education (NASBE, 2013). Presently, three states—Illinois, Kansas, and Pennsylvania—have adopted comprehensive SEL standards with developmental benchmarks.

Research has demonstrated a connection between OTL and SEL variables on one hand, and student standardized test scores on the other. In a study of Chicago schools, Erbe (2000) found that “focus on learning,” “school commitment,” and “parental involvement” had roughly .5 to .7 correlations with math achievement. Some studies have also shown that specific school resources (e.g., funds used to support targeted instruction) have an effect on achievement (Archibald, 2006; Lavy, 2012), though such findings are not universally true across the scholarly literature (e.g., Hanushek, 1997, 2003; Houtenville & Conway, 2008). Numerous other studies document the connections between various measures of school quality and outcome measures of student achievement (Berkowitz, Moore, Astor, & Benbenishty, 2017; Cadima, Peixoto, & Leal, 2014; Darling-Hammond, 2000; Kutsyruba, Klinger, & Hussain, 2015; Lubienski, Lubienski, & Crane, 2008).

Still, it seems unwise to validate various measures of school quality solely by establishing relationships with standardized achievement scores. Perhaps the most compelling argument against such a practice is the fact that different domains of school quality may be orthogonal, which is to say that successes in some areas may not coincide with successes in others. The most relevant research in this area comes from investigations into teacher effectiveness. Jackson (2016), for instance, found that teachers exhibit variability in their effect on student behaviors, including suspensions, attendance, course grades, and on-time grade progression, as well as longer term outcomes such as high school completion. Furthermore, these teacher effects on nontest score outcomes exhibit only weak positive correlation ($\rho = .16$) with a teacher’s value added to standardized achievement. A comparable study, which uses data from more than 1 million students in the Los Angeles Unified School District, reaches similar conclusions about the multidimensionality of teachers (Petek & Pope, 2016). In other words, teachers can be relatively strong in raising student achievement without improving student behavioral outcomes, and vice versa. These and other studies (e.g., Grissom, Loeb, & Doss, 2015) provide compelling evidence that teacher effectiveness is not a unidimensional construct, which in turn suggests that school quality is not either.

A number of districts are currently employing school quality frameworks (SQFs) that extend beyond academic achievement by including measures of OTL and/or SEL. The Chicago Public Schools, for instance, have worked with the University of Chicago’s Consortium on School Research to employ the 5Essentials framework. This framework measures the effectiveness of

school leaders to implement a clear and strategic vision, the level of support for teachers, the involvement of families, the safety and orderliness of the school, and the level of academic challenge in classes. Recently, the entire state of Illinois adopted the framework, making the case that “test scores alone do not provide a full picture of teaching and learning in any one school” (5Essentials, n.d.). The 5Essentials survey is taken by all pre-K through 12th-grade teachers, as well as by all sixth- to 12th-grade students in Illinois, and reports generated from these surveys are produced for all schools in the state.

Similar work is currently being done by the California Office to Reform Education (CORE)—a consortium of districts that collectively educate more than 1 million students in the state. CORE’s School Quality Improvement Index is built around a 100-point scale: 60 points allotted for the academic domain, and 40 for social-emotional and school culture factors. Within the academic domain, two thirds of points are determined by test scores, with raw scores and growth scores counting equally. The remaining third of the academic domain is determined by graduation rates. For the 40 points allotted to social-emotional and school culture factors, the CORE districts rely on a broader range of measures, including how many students are missing significant amounts of school, how many are suspended or expelled, and how many English language learners have become fluent. In addition, the CORE districts plan to incorporate results from school climate surveys given to students, parents, and teachers—a practice that is increasingly supported by research (e.g., Kane & Staiger, 2012; Wilkerson, Manatt, Rogers, & Maughan, 2000).

Given criticism from scholars and the public, as well as new flexibility afforded by ESSA legislation, it appears that state-level measurement and accountability systems will expand in coming years. As they do, it seems likely that they will include many of the input measures that fall under the umbrella of OTL, and also many of the outcome measures included in SEL frameworks.

Current Study

Study Population

This project took place in a diverse, mid-sized urban district in the state of Massachusetts. In the 2014-2015 school year, nearly half of students in the district were Hispanic, roughly a third were White, and the remaining students were mostly Asian and African American (Massachusetts Department of Elementary and Secondary Education, 2016). The district had nearly 5,000 students spread out across its one early learning center, seven traditional primary schools, two alternative schools, and one secondary school. The district

serves a fairly high-need population, with more than one third of students being deemed economically disadvantaged (ED) and nearly one in five being categorized as an English language learner.

The “Beyond Test Scores” Project

In the spring of 2014, our research team partnered with the district, which was interested in measuring school quality “beyond test scores.” District administrators, the city’s school committee, and other civic leaders had expressed frustration with a narrow range of measures, which they argued had limited their ability to track progress across many aims, and which appeared to correlate strongly with student socioeconomic status. A number of stakeholder groups expressed their particular interest in expanding the current conception of school quality to include OTL and SEL measures.

Our team began by compiling an inventory of school quality factors distilled from national polling, educational research, and community surveys. This generated a list of several dozen potential variables. Some of these variables repeated each other, differing primarily in the language used to express them. In those cases, we simply selected the factor with the clearest wording. In addition, many factors on the list seemed to be of different grain size—some, for instance, were quite specific, while others seemed to be umbrella concepts for multiple factors. In those cases, we retained the smaller, specific items, and set aside the umbrella terminology for later in the process.

Having distilled 32 separate factors for a SQF, we organized them into a hierarchical taxonomy. In doing so, we paired together similar metrics, such as “student sense of belonging” and “student-teacher relationships,” into measures—in this case, “Relationships.” Next, we nested our 16 subcategories under five major categories. The “Relationships” measure, for instance, together with “Safety” and “Academic Orientation,” formed a major category: “School Culture.” This approach allowed us to preserve a high level of complexity, while also respecting the limits of working memory (Baddeley, 1992; Cowan, 2001).

Throughout this process, we conducted focus groups with stakeholders in the community. Ultimately, we conducted 10 focus groups—three with teachers, two with principals and administrators, and five with parents and community members. Although educators, administrators, and laypeople have different priorities and concerns, these different constituencies were able to agree on a single framework. As one of our research assistants concluded in a memo analyzing results from focus groups with principals and community members: “There was virtually no disagreement between the two groups.” We found similarly strong overlap with results from our

focus groups with teachers. No longer hearing new suggestions from our stakeholders—a point of “saturation” (Morse, Barrett, Mayan, Olson, & Spiers, 2002) in our sampling—and seeing no major disagreements among them, we sent a copy of the framework to district leaders for their approval and adoption. Note that the information gathered in these focus groups was used to engage and inform stakeholders in the construction and validation of the alternative framework; they did not serve as a collection point for the school quality data that are analyzed in this study. See the appendix for a copy of the SQF, which outlines all metrics that are hierarchically combined to construct the framework. For those who wish to understand the SQF in greater detail, see Schneider (2017) for information regarding the creation of the SQF and the use of focus groups in that process.

Our purpose of this article was not to make claims about the effectiveness or generalizability of this framework. Instead, we have provided an overview of its design to show that it is an adequate test case for the state-level measurement and accountability systems that will emerge in coming years. It includes many of the most commonly discussed OTL measures, as well as a number of SEL measures. In addition, its development incorporated the feedback and multiple stakeholder groups, and to a large degree addresses the public concerns that led to changes in federal law pertaining to school accountability.

Data and Method

There are three primary sources of data used in this study: a survey of students in the district, a survey of teachers in the district, and a collection of administrative data made available by the district. The unit of analysis in this study is the school. The sample includes seven elementary/middle schools, five of which are pre-K-8, one of which is K-8, and one of which is K-6. To ensure comparability, the only high school in the district was excluded from analysis, as were an early childhood center and two small alternative schools. These excluded schools serve unique populations, and therefore do not lend themselves to norm-based comparison with the included schools.

Students in Grades 4 and above at each of the elementary/middle schools were issued perception surveys, with students in Grades 3 and below being excluded due to concerns of age appropriateness, specifically with regard to reading comprehension level. The survey produced a student sample of 1,607 students or 98.2% of nonexcluded population. The teacher survey was issued to and completed by all 229 teachers within the sample schools. Administrative data were collected at the end of the academic year for all schools in the sample.

Surveys were constructed using established scales when available. The internal consistency of all survey scales was examined, and Cronbach's alpha was calculated for all scales. To examine the relationship between data sources, all metrics were normalized to have a mean of 0 and a standard deviation of 1.0. Thus, the analytic approach used in this study includes district-normed measures. Consequently, school quality is calculated in comparison with other schools within the district analytic sample. In other words, a zero-sum approach is taken, where a school's quality is judged with respect to how the other schools in the district perform within a given metric.¹

We examine the correlations of metrics within the five major categories of school quality in our framework. Note that all correlations presented in this article are at the school level, which aligns with our interest in understanding how factors of school quality relate. We then sum all metrics within a given school measure to form a single rating for that school quality measure—first at the submeasure level, then at the measure level, and finally at the major category level.

Next, we examine the correlations between major school quality categories. We generally expect to see positive correlation, as schools that perform well in one domain might be expected to succeed in others as well. However, we do not anticipate strong correlations, as a general rule, as we also expect that schools will exhibit relative strengths and weaknesses. Again, there are theoretical reasons to suspect that different measures of school quality are orthogonal to various degrees, so one would expect commensurate empirical variability as well. We then form a composite (i.e., overall) SQF ranking by summing combined *z* scores over all categories. This allows us to examine how school rankings might differ across the alternative and traditional frameworks. We then dive deeper into these relationships, reporting the average school-level correlations between SQF metrics and the state's Progress and Performance Index (PPI), which is currently used by the Department of Elementary and Secondary Education to rate schools, and which is discussed in greater detail later in the article.²

Finally, we examine the relationship between each system (the existing state accountability system and the alternative SQF system) and school poverty. To do so, we calculate the average school-level correlations between the state PPI system and school poverty, using the percentage of ED students in each school. We then perform the same calculation for the SQF metrics, reporting average correlations for each of the major categories in the SQF to illustrate which domains of the alternative framework mirror school poverty, and which do not. Through these analyses, we address two primary research questions:

Research Question 1: To what extent does a more holistic array of school quality data capture information not reflected in current accountability systems? Specifically, what are the correlations between SQF metrics and the Massachusetts PPI, and how might school rankings differ under the two frameworks?

Research Question 2: How might existing data systems reflect the out-of-school context tied to student demography, rather than something about school quality? Specifically, what are the correlations between SQF metrics and school poverty, and how do those compare with the correlation between PPI and school poverty?

Findings

Scrutinizing the Alternative Framework

Before conducting the analyses that directly address our research questions, we examined the measures employed in the alternative framework to confirm that they met basic standards. We performed factor loading for the 22 survey-based metrics, calculating the internal consistency of this composite using Cronbach's alpha. We found that 20 metrics exceeded .7—long held as a rule of thumb in scale reliability (Nunnally, 1978)—the remaining two survey scales exhibiting reliability estimates of .69 and .58. Two survey-based metrics—Arts Exposure (5Cia) and Physical Activity (5Diia)—were based on a single survey question, and therefore did not have associated reliability statistics. We consider these results to be sufficient to conduct the subsequent analyses necessary for this study.

Schools exhibited considerable variation in most metrics (see Table 1), as indicated by standard deviations between 0.16 and 1.2 for teacher survey metrics, and 0.09 and 0.46 for student survey metrics, on a 5-point Likert-type scale. The remaining six metrics, which were taken from district administrative records, also displayed meaningful variation in our sample. Given the norm-referenced approach to this study, such variation is a necessary precondition for the remaining analyses.

To illustrate the relationship between the metrics that form school quality categories, we take the within-category average of metrics-level correlations. The average within-category correlations are shown in Table 2, and range from .15 (Category 3, Resources) to .45 (Category 2, School Culture). These weak-to-moderate average correlation magnitudes generally support the grouping of such metrics to form school quality categories, as they show a positive, but not deterministic, relationship between these related measures.

Table 1. Descriptive Statistics, Standardized School Quality Metrics.

	Source	Average school z score	Minimum school z score	Maximum school z score	Standard deviation
Professional Preparation Scale (1Aic)	Teacher survey	0.03	-0.34	0.42	0.26

Positive Affect Scale (5Dia)	Student survey	0.02	-0.30	0.29	0.19
Physical Activity (5Diiia)	Teacher survey	-0.01	-0.28	0.32	0.23

We next analyze the relationships between, as opposed to within, the five major categories of school quality in the SQF. To do so, we aggregate all normalized metrics to form a single categorical school quality score. In an effort to evenly weight categories, we aggregate from lower levels upward. For example, by combining the Class Size ratio metric (3Biiia) with the Class Size Scale metric (3Biiib), we formed a single submeasure: Class Size (3Bii). Then, we combined Curricular Strength (3Bi) with Class Size (3Bii) to form

Table 2. Average Within-Category Correlations of School Quality Metrics.

Major school quality category	Average within-category metric correlation
Teachers and the Teaching Environment (1)	.33
School Culture (2)	.45
Resources (3)	.15
Academic Learning (4)	.17
Character and Well-Being (5)	.17

Table 3. Correlations of Main Categories of School Quality.

	Teachers and the Teaching Environment (1)	School Culture (2)	Resources (3)	Academic Learning (4)	Character and Well-Being (5)
Teachers and the Teaching Environment (1)	1				
School Culture (2)	.64	1			
Resources (3)	.34	.20	1		
Academic Learning (4)	.29	.70	.66	1	
Character and Well-Being (5)	.66	.49	.18	.28	1

Table 4. Rankings, PPI (State Percentile in Parentheses), SQF Categories (z Score in Parentheses), SQF Composite Score (Combined z Score in Parentheses).

School	Massachusetts PPI	Teachers and the Teaching Environment (1)	School Culture (2)	Resources (3)	Academic Learning (4)	Character and Well-Being (5)	SQF Composite
T	1 (89)	2 (0.22)	1 (0.46)	1 (0.44)	1 (0.55)	5 (0.01)	1 (1.69)
U	2 (75)	5 (-0.05)	5 (-0.03)	2 (0.31)	3 (0.11)	3 (0.07)	2 (0.41)
V	3 (73)	6 (-0.26)	4 (0.046)	5 (-0.22)	2 (0.13)	4 (0.03)	6 (-0.26)
W	4 (53)	1 (0.28)	2 (0.33)	6 (-0.25)	6 (-0.17)	1 (0.10)	3 (0.28)
X	5 (50)	7 (-0.30)	7 (-0.39)	4 (-0.14)	7 (-0.33)	7 (-0.16)	7 (-1.31)
Y	6 (44)	4 (-0.04)	3 (0.12)	7 (-0.27)	4 (-0.00)	6 (-0.01)	5 (-0.20)
Z	7 (31)	3 (0.14)	6 (-0.25)	3 (0.09)	5 (-0.15)	2 (0.07)	4 (-0.11)

Note. PPI = Progress and Performance Index; SQF = school quality framework.

a single measure: Curricular Resources (3B). Finally, we combined relevant measures to create a major category score—in this case, combining Facilities and Personnel (3A), Curricular Resources (3B), and Community Support (3C) to form Resources (3). Table 3 shows the Pearson correlation coefficients at the category level. All correlations shown in Table 4 are positive,

with magnitudes varying from .18 to .70. Overall, these findings suggest that categories used to construct the framework exhibit meaningful associations, while not being deterministically related.

Relationships Between the Alternative Framework Metrics and the State System

School rankings. One common criticism of existing data systems is that they fail to measure many valued aspects of school quality. We now turn to our first research question, initially by exploring how school rankings might align and diverge under the two different frameworks. Specifically, we sought to determine if the holistic picture of school quality is somehow being captured by the current PPI, which is used by the Massachusetts Department of Elementary and Secondary Education to classify schools into one of five accountability and assistance levels. The PPI is a single number between 0 and 100, produced by combining test score results—specifically progress toward 100% proficiency, as well as average test score improvement measured by the state’s Student Growth Percentile (SGP)—along with graduation and drop-out rates. It is possible, after all, that while the information may not be *presented* in the PPI system, it is nevertheless *accounted for*. Table 4 lists the seven study schools in order of their PPI ranking. Presented alongside this ranking scheme are six alternative rankings—ranked, respectively, by each of the five major categories of the alternative SQF model, as well as by the composite, or summative *z* score, of those five categories.

Overall, we see some agreement in overall rankings between the two frameworks. Two schools (T and U), for instance, maintain their relative place when comparing the state PPI ranking with the alternative composite SQF ranking. Two schools (W and Y) move one place, while one school (X) moves two places when switching from the PPI model to the SQF model. Two schools moved three spots. School V, which was third according to the PPI, was sixth in the composite SQF model, as it had relatively low scores in all categories except Academic Learning; school Z jumped from seventh place to fourth. It is worth noting here that some categories drive overall SQF rankings much more than others. School Culture, for instance, exhibits a range of 0.85 *SD* across the seven schools. By contrast, the highest and lowest scoring schools in the Character and Well-Being category are separated by only 0.26 *SD*.

Perhaps, the most important aspect to focus here, however, is not the overall congruence in rankings between frameworks but rather the variability across individual measures that speaks to the multidimensionality of school quality. As seen in Table 4, positional changes are more substantial within individual categories than in the composite of all five. Schools W and X, for

instance, are quite similar in terms of PPI rankings—placing in the 53rd and 50th percentiles, respectively. Yet, differences abound. School W ranks first in both Teachers and the Teaching Environment and in Character and Well-Being outcomes; it also ranks second in School Culture. School X, by contrast, ranks last in all three of those categories.

Overall, we find that school rankings according to the PPI and SQF models exhibit some approximate alignment, with a few notable exceptions. Perhaps, the most important takeaway, however, is that examining only a single index measure—either the PPI or the composite SQF—obscures the fact that some schools perform well in some domains while doing relatively poorly in others. Furthermore, the SQF provides a rich set of indicators which schools might use to help guide policy and improvement efforts; the same cannot be said of the PPI.

SQF metrics and PPI. We now explore our first research question more deeply, reporting on correlations between individual metrics from the more comprehensive SQF and the state system to understand what specific information is not being captured by the PPI calculation (see Table 5). We find considerable variability not only in the relationships between individual metrics and the PPI but also between PPI and the average correlations of major categories of the SQF. Moreover, the strengths of the relationships between various SQF metrics and PPI offer suggestive evidence as to the ways in which PPI may inadequately measure a fuller conception of school quality. In general, we find that this relationship is usually stronger when a metric was related to student achievement or family background, and lower when it was more a reflection of educational opportunity.

Metrics within the Teachers and the Teaching Environment category exhibit an average correlation of .08 with the PPI. In addition, metrics within this category have very different associations with the PPI. Three metrics within Teachers and the Teaching Environment exhibited moderately negative correlations: teacher perceptions of the usefulness of professional development, student perceptions of the level of teacher interest in students, and principal leadership. In other words, teachers in lower PPI schools exhibited greater interest in students, as measured by student perception surveys, and also found their professional development to be more useful. This serves as a powerful instance of the ways in which a more holistic measure of school quality—and the quality of the teacher environment, specifically—may capture important aspects of the schooling enterprise which are not included in current measurement and accountability frameworks. Put another way, relationships between test scores and other school quality variables are not always strong, and specific strengths and weaknesses may be hidden even if an aggregate relationship is positive.

Table 5. Pearson's Correlation Coefficients Between SQF and the Massachusetts PPI, Rate of ED Students.

		Pearson's correlation coefficient	
	Metric	PPI percentile rank	% ED students
Teachers and the Teaching Environment	Professional Preparation Scale (1Aic)	.86	-.92
	Pedagogical Effectiveness Scale (1Aia)	.51	-.71
	Interest in Students Scale (1Aiiia)	-.36	.02
	Teacher Turnover (1Bia)	.14	-.51
	PD Scale (1Biib)	-.47	.14
	Teacher Principal Trust Scale (1Biiia)	.06	-.42
	Principal Instructional Leadership Scale (1Biiib)	-.19	-.32
	Average Correlation for Category 1 Metrics	.08	-.39
School Culture	Student Safety Scale (2Aib)	.91	-.74
	Peer Victimization Scale (2AiiB)	.73	-.92
	Peer Support Scale (2AiiC)	.27	-.75
	Sense of Belonging Scale (2bia)	.02	-.39
	Student Teacher Relationship Scale (2Biia)	.65	-.82
	Chronic Absences (2Cia)	.29	-.62
	Academic Press Scale (2CiiA)	.58	-.59
		Average Correlation for Category 2 Metrics	.49
Resources	Art Classes per Student (3Aia)	-.02	-.05
	Counselor per Students (3AiiB)	.74	-.53
	Support Staff Scale (3AiiD)	-.05	-.34
	Curricular Strength Scale (3Bif)	.31	-.80
	Class Size (3Biia)	-.40	.41
	Class Size Scale (3Biib)	.28	-.04
	Parental Engagement Scale (3Cia)	.71	-.76
	Community Engagement Scale (3CiiA)	.46	-.58
		Average Correlation for Category 3 Metrics	.25
Academic Learning	State SGP Score (4Aia)	.61	-.33
	Student Achievement Scale (4AiiA)	.77	-.99
	Student Engagement Scale (4Bia)	-.22	-.07
	Valuing Learning Scale (4BiiA)	-.27	-.02
	Problem-Solving Scale (4Cia)	.76	-.95
	Average Correlation for Category 4 Metrics	.33	-.47
Character and Well-Being	Appreciation for Diversity Scale (5Aia)	.76	-.43
	Grit Scale (5Bia)	-.32	.19
	Arts Exposure (5Cia)	-.10	-.25
	Positive Affect Scale (5Dia)	.00	-.36
	Physical Activity (5Diia)	-.08	-.53
		Average Correlation for Category 5 Metrics	.05
	Average correlation for all metrics	.25	-.44

Note. PPI = Progress and Performance Index; SQF = school quality framework; ED = economically disadvantaged.

We find that School Culture metrics exhibited the strongest relationship to PPI, with an average correlation of moderate magnitude ($\rho = .49$). Given the robust association between school climate and achievement (Thapa, Cohen, Guffey, & Higgins-D'Alessandro, 2013), such a finding was anticipated. The seven individual metrics that form School Culture—taken from the teacher survey, student survey, and district administrative data—all exhibit positive associations with state PPI, although the magnitude of these correlation coefficients varies widely. This suggests that even in the case where broader constructs exhibit a strong connection to the PPI, the metrics composing the broader construct are likely to behave differently.

On average, the metrics forming the Resources category displayed weak-to-moderate positive correlations ($\rho = .25$) with PPI. Within Resources, the parental engagement and community engagement scales—both drawn from the teacher survey—exhibited strong and moderate correlations, respectively, with the state PPI calculation. This might not be surprising, given that student achievement is strongly influenced by home and community effects that might be reflected in these engagement scales. A number of metrics within the control of the school, however, had negative correlations with PPI; these metrics were art classes per student, the support staff scale, and class size. The near-zero relationship between PPI and art classes per student is to be expected, given that PPI likely does not capture the benefits of arts education. These findings suggest that Resources, which generally reflect OTL concepts more than outcome-based indicators of school quality, are not captured very well by the PPI.

Academic Learning metrics and PPI were also weakly to moderately correlated ($\rho = .33$). However, when one looks at metric-level correlations within the Academic Learning category, a compelling trend emerges. Three metrics were strongly correlated with PPI. The first of those, the state SGP, is one of four components of the PPI. Consequently, the strong correlation between the two is to be expected. Similarly, the Student Achievement Scale—a teacher survey measure that captures perceptions about student work ethic and performance—and the Problem-Solving Scale—measuring teacher perceptions of student higher order thinking skills—also correlate highly with PPI. However, two metrics exhibited a negative correlation with PPI: the student engagement and valuing learning scales, both of which seek to measure student connectedness to learning. One may view these latter two metrics as reflecting an OTL, whereas the former three metrics better capture the level of student performance. Thus, this finding suggests that PPI may be capturing student performance without doing a particularly good job of representing the extent to which teachers provide students with a chance to learn by getting students engaged in the process of their own learning. In fact, schools that perform better on student achievement might be *damaging* the intrinsic value of learning in the process.

Metrics within the Character and Well-Being category, on average, exhibit near-zero correlation ($\rho = .05$) with the PPI. This is largely due to one metric—appreciation for diversity—having a strong positive correlation, and the remaining four metrics exhibiting negative correlations to PPI. Somewhat surprisingly, schools in the district exhibited very little variability on metrics within Character and Well-Being category. In other words, while schools differ dramatically according to the PPI, they look remarkably similar when comparisons are made using SEL indicators. This may be due to the fact that the district exerts a stronger influence than the school in this domain, or it may be due to measurement error. Whatever the case, though, it seems to call for more thorough investigation.

Relationships Between the Alternative Framework Metrics and School Poverty

One of the strongest criticisms of existing data systems is that they unintentionally capture out-of-school factors tied to student demography. In other words, rather than measuring schools, they are measuring families and neighborhoods. Here, we answer our second research question by examining whether SQF metrics relate as strongly to school poverty as does the existing state PPI score, which is heavily reliant on raw standardized test scores.

The Massachusetts PPI calculation exhibits a very strong negative correlation ($\rho = -.80$) to the percentage of ED students in a school, while the relationships between SQF metrics and percent ED vary in magnitude (see Table 5). Overall, the average correlation for all metrics ($\rho = -.44$) is roughly half as large as the correlation between PPI and ED rates. In three major categories—Teachers and the Teaching Environment, Resources, and Character and Well-Being—we see, on average, moderate negative correlations to ED rates. While several metrics within these categories are, in fact, tightly tied to school poverty—for example, Professional Preparation ($\rho = -.92$), Curricular Strength ($\rho = -.80$), Parental Engagement ($\rho = -.76$)—most exhibit more moderate correlations. In fact, five of the 20 metrics from these categories (Interest in Students, PD Scale, Art Classes per Student, Class Size Scale, Grit Scale) exhibit near-zero or slightly positive correlations, while Class Size has a positive correlation with ED rates of moderate magnitude ($\rho = .41$), representing an important investment made by the district into its poorest schools. Unsurprisingly, each of these five metrics reflect OTL or SEL themes more so than absolute student academic performance. Conversely, we find School Culture metrics to be consistently and strongly tied to school poverty.

The most interesting trends to emerge from this particular analysis are seen in the correlation coefficient between ED rates and Academic Learning measures. Two metrics—the Student Achievement Scale and the Problem-Solving

Scale—exhibit near-deterministic relationships with the percentage of ED students in a school, with correlation coefficients of $-.99$ and $-.95$, respectively. The state SGP score, which, roughly speaking, measures achievement growth and not absolute achievement, still exhibits a negative correlation of moderate magnitude ($\rho = .33$). However, two metrics within Academic Learning (Student Engagement Scale, Valuing Learning Scale) have essentially no relationship to school poverty. Given that these latter two variables are closer representations of opportunity-to-learn (student perceptions of their engagement in class, teacher perceptions of whether students value learning), and further from the more absolute learning metrics that comprise this category (teacher perceptions of student ability to achieve, problem solve), this provides a compelling example of how a holistic accountability system provides a more complete picture of quality for those schools serving vulnerable students.

Discussion

Measurement systems shape school priorities, inform policy, and affect parental behavior. They also constitute the basis for accountability structures. This study examines how the current system used to identify school quality in Massachusetts—the PPI—compares with a comprehensive alternative system that may prefigure accountability systems of the future. Specifically, we examine what the state model fails to capture, as well as what it captures but should not. We find that the PPI calculation does roughly align with a more comprehensive framework. However, the PPI system suffers from several weaknesses previously identified by scholars, educators, and the public: It offers only summative information that cannot be used for school improvement, it fails to capture information about the OTL and social-emotional learning, and it strongly reflects school demographics. By contrast, the SQF model—as an example of what accountability systems of the future might look like—is less prone to these particular shortcomings. Moreover, whereas the current system of accountability is run by the state, a system like that of SQF—one which is more responsive to the values and concerns of local stakeholder groups—would be more likely to empower the community to drive meaningful school reform. This is especially the case if data are made easy to access and interpret.

This study may strengthen the hands of those who have identified weaknesses in current approaches to measurement and accountability. For, while there is much agreement that current systems are inadequate, we know relatively little about the degree to which an alternate system would offer an improvement. As evidence from this study appears to indicate, a model that includes a broader range of metrics represents a significant step forward.

What Is Not Measured by Current Systems

One important theme to emerge from this work is that the current accountability framework in Massachusetts—typical of such frameworks in other states—does not capture all of the elements of school quality that stakeholders deem to be important. Although we find that PPI is positively related to each of the five measures we use to define school quality, this relationship is quite weak in some cases, and numerous important metrics are actually inversely related to PPI. Even when looking only at the metrics which comprise the Academic Learning category of the alternative SQF model, we see a range of associations which might indicate that PPI fails to capture certain components of academic achievement. There are a number of important practical and political implications that follow from this.

School Rankings. This work documents the multifaceted nature of school quality, and reveals some of the nuance lost when school quality is presented as unidimensional. In cases where ranking must be done to identify low-performing schools, it is important to note three things: First, identified schools may have different strengths and weaknesses. Second, some domains of school quality may differentiate schools quite well, while others may be relatively consistent across schools. Third, regardless of the methodology used to rank schools, one should acknowledge that rankings are highly dependent on the metrics that are chosen for inclusion, and that such choices involve a subjective component.

Policymakers, of course, do not have to rank schools. But if they are going to, such a high-stakes practice demands a more complete accounting of school quality.

Gaming. A second policy implication relates to the unintended consequences of measurement systems. Critics argue that traditional accountability systems, being heavily reliant on a single measure, may promote gaming. That is, they may encourage schools to improve their scores on a performance indicator without actually improving their overall performance. So, while it may sometimes be the case that rising test scores indicate gains in student learning, it might also be the case that rising scores indicate a narrowing of the curriculum or an increased emphasis on test-preparation techniques—practices that would accomplish the same end by different (and problematic) means. Consequently, it appears to be in the best interest of students to create a system that is harder to game.

As a holistic system has far more indicators, and its constituent metrics are not deterministically related to each other, it appears less likely that

such gaming behaviors would develop. That said, the strongest incentive to game performance indicators may be high-stakes accountability itself, which places tremendous pressure on schools to achieve measurable results. Insofar as that is the case, policy leaders may wish to revisit not only the performance measures they include in accountability systems but also the stakes attached to those systems.

Actionable data. One of the goals of any accountability system should be to provide useful information to stakeholders. Given that individuals may differentially value particular aspects of school quality, it seems important to report on multiple measures. A more comprehensive school quality measure is more likely to align with the interests of the public and to provide them with actionable information. It is also likely to provide schools with more information. When schools are able to see how they compare with each other along a range of metrics, as opposed to merely achievement, leaders are more apt to make judgments based on such data.

What Is (But Should Not Be) Measured by Current Systems

In addition to current accountability systems failing to measure certain aspects of schooling, they indirectly measure family and neighborhood characteristics. Although demography is not destiny and though schools with similar poverty levels do vary in their ability to improve student outcomes, the relationship between school poverty and accountability ratings is quite strong. Two important implications flow from our finding.

Perceptions of school quality. Current accountability systems are highly reliant on test scores. Insofar as perceptions of school quality are shaped by such systems, then, they will be strongly influenced by student poverty. Perceptions of school quality matter enormously, likely driving a subset of teachers and parents toward higher achieving schools and away from those identified as struggling. It seems quite possible that such a Matthew Effect would increase inequality in public education, with systems of accountability perversely hurting the very schools they were established to help.

We find variability in the relationship between SQF metrics and school poverty, and observe that, on average, the magnitude of this correlation is half as large as that between the state accountability system and school poverty. The inclusion of a more comprehensive set of indicators, it seems—particularly if they were less tightly coupled with socioeconomic variables—might help highlight the ways in which schools serving historically marginalized groups are, in many cases, doing rather well.

Capacity building. Under an alternative accountability system, the relative strengths and weaknesses of schools are more likely to emerge. Indeed, this analysis reveals important areas where schools with low test scores perform roughly on par with (or better than) higher scoring schools. This is not to say that we should be sanguine about low test scores. Although test scores are limited indicators of school quality, they do indicate something about basic literacy and numeracy, and by extension, about a core function of public education. For the past two decades, however, low test scores have been viewed as the sign of a failing school and have served as the basis for sanctioning the schools most in need of assistance. A more holistic framework, which more clearly identifies strengths and weaknesses, and which identifies inputs alongside outputs, may help shift accountability systems away from punishing schools and toward capacity building. If it is possible to determine where and why a school is weak, and if it is clear that the school is not uniformly underperforming, it may seem less reasonable to label it failing or to slate it for closure.

It is worth noting here that, although schools with low test scores have been more effected than those with relatively high scores, a more holistic measurement system might benefit *both* groups of schools. As we find in this study, schools are not uniformly good or bad. Thus, schools with high standardized test scores may have areas of relative weakness that have been overlooked and therefore unaddressed. Seeing schools with more nuance, then, may lead to more emphasis on capacity building, whether student standardized test scores are high or low.

Limitations

The data used in this study come from the initial pilot year of an initiative to create a more holistic measure of school quality, using a new framework that may be refined and expanded upon in subsequent years. There are clearly numerous concerns that must be evaluated before any new metric should be used in a high-stakes accountability system, including the benefits and drawbacks of expanding school quality measures, as well as possible unintended consequences of doing so. In addition, no alternative accountability framework will reflect stakeholder values perfectly, even one like the SQF, which was developed in collaboration with local stakeholders. This study also examines only seven schools in a single district, all of which are subject to a single-state accountability scheme. Moreover, this sample is restricted to traditional primary/middle schools, and only students in Grades 4 and above were surveyed; we do not include any early education centers, high schools, or alternative schools in our analyses. Overall, then, one should be very

cautious about generalizing the findings presented here to other schools. That said, given the dearth of research on this topic, as well as largely similar incarnations of accountability across states in the nation, the findings here are seemingly germane to a wide audience.

Conclusion

The recent authorization of ESSA will likely spur the inclusion of additional school quality metrics in measurement and accountability systems, most likely in the form of opportunities to learn and socioemotional learning. The findings in this study support the continued exploration of a more holistic measure of school quality. Current accountability systems measure too little about schools, and too much about families and neighborhoods.

Insofar as accountability systems seek to encourage efficient and effective use of resources, it seems they have much to gain from the kinds of improvements described here. But we must recall that accountability systems in education are also intended to promote equity for our most vulnerable students who deserve a fair and adequate education. For this task, current measurement and accountability systems appear even less up to the task. By stigmatizing and sanctioning low-achieving schools without understanding how well such schools perform across their full mission, we exacerbate inequality of opportunity. Those harmed, as a result, are those most in need of our care.

The accountability system of the future, if it looks like what we imagine, will not be perfect. But it does represent a significant improvement. Policymakers should take seriously the challenge of moving forward, and revising existing measurement and accountability systems. And, as they do, they should remember that an even more perfect system lies even further ahead. Beyond each mountain, another mountain.

The author(s) declared no potential conflicts of interest with respect to the research, authorship, and/or publication of this article.

Funding

The author(s) received no financial support for the research, authorship, and/or publication of this article.

Notes

1. Although steps are being taken to produce criteria-based measures of school quality for this district, our lens in this study is norm referenced. Thus, both the school quality framework used here and the state Progress and Performance Index (PPI) compare schools with each other. Given the nature of this project, we are limited to comparisons between schools within the district.
2. For more information on PPI, see <http://profiles.doe.mass.edu/accountability/report/aboutdata.aspx>
